Abstract:
The purpose of this paper is to obtain the simulation results on a dc motor control system with a basic Fuzzy logic controller (FLC). In this era the need for electric driven vehicle has increasing rapidly due to the global warming problem. The traditional Proportional-Integral (P-I) controller, which has been widely used for the speed control of dc motor drives, has been compared with the relatively new Integral-Proportional (I-P) controller which first discussed in the year of 1978. P-I controller is used to control the speed of DC Motor. A model is developed and simulated using MATLAB/SIMULINK. However, the P-I controller has some disadvantages such as: the high starting overshoot, sensitivity to controller gains and sluggish response due to sudden disturbance. So, the relatively new Integral-Proportional (I-P) controller is proposed to overcome the disadvantages of the P-I controller. This paper presents some improvements in this important field of industries. The result of simulation and experimental indicate the superiority of (I-P) controller over (P-I) controller. The proposed controller results in reduced oscillations around the set point which are present in system with a basic fuzzy logic controller. I-P and P-I both are using widely in this decade.

Keywords:
DC motor drive, speed control; Integral-Proportional I-P controller; Proportional-Integral P-I controller; Fuzzy logic controller

INTRODUCTION

Because of their high reliabilities, flexibilities and low costs, DC motors are widely used in industrial applications, robot manipulators and home appliances where speed and position control of motor are required. PID controllers are commonly used for motor control applications because of their simple structures and intuitionally comprehensible control algorithm. These Conventional dc motors are highly efficient and their characteristics make them suitable as servomotor. However, its needs a commutator and brushes which are subject to wear and required maintenance. The functions of commutator and brushes were implemented by solid-state switches that can realize maintenance-free motors. These motors are now known as brushless dc motors. Brushless dc motors are widely used in various applications. Two examples of them are electric vehicle and industrial machinery. Fuzzy logic controller (FLC) which is presented by Zadeh in 1965, is a new controller [1]. Besides that, FLC is more efficient from the other controller such as P-I controller. The comparison between them is needed to compare what the controller is efficient [2]. The reason why conventional controller low efficiency such as P-I controller because the overshoot is too high from the set point and it may takes delay time to get constant and sluggish response due to sudden change in load torque and the sensitivity to controller.

II. MATHEMATICAL MODELLING

The P-I controller has a proportional as well as an integral term in the forward path, the block diagram with a P-I controller for a dc motor drive is shown in Fig. 1. The integral controller has the property of making the steadystateerror zero for a step change, although a P-I controller makes the steady-state error zero, it may take a considerable amount of time to accomplish this. Fig. 2 shows I-Pcontroller along with a dc motor drive, where the proportional term is moved to the
feedback path and it acts like feedback compensation. The analysis in S-domain is discussed in this section to study the transient and steady-state behaviour for both controllers.

From (1) and (3), P-I and I-P controllers have the same characteristic equations, and it can be seen that the zero introduced by the P-I controller is absent in the case of the IP controller. Therefore the overshoot in the speed, for a step change in the input reference R(S) is expected to be smaller for the I-P control.

III. SPEED CONTROL SYSTEM USING A BASIC FUZZY LOGIC CONTROLLER

The block diagram of the dc motor control system with a basic FLC is shown in Fig. 3. The basic FLC consists of the following four blocks [6]:

- Fuzzifier which converts input data (error and error rate) into suitable linguistic values.
- Knowledge base which consists of a data base with necessary linguistic definitions (rule set).
- Defuzzifier which produces a non-fuzzy control action that represents the membership function of an inferred fuzzy control action.
- Decision making logic which is used to decide what control action should be taken.

Defuzzification is done using the Center-of-gravity method in which the inferred (numerical) value of the

\[ u = \frac{\sum m_i T_j}{\sum T_j} \]

where \( m_i \) are the singletons and \( T_j \) are the corresponding degree of fulfilment.

The output of the controller is the change in motor voltage \( A V_c \). The linguistic variables for the input and output set are Negative Large (NL), Negative Small (NS), Zero (Z), Positive Small (PS), and Positive Large (PL) as shown in Fig. 4. The rule base used in the design of the FLC is shown in Fig. 5. The location of the singletons are the centers of gravity of the triangular sets that are -3, -1, 0, +1, t3 for NL, NS, Z, PS, PL respectively.

The state space model of the dc motor used in the simulation is given by:

\[
\begin{bmatrix}
i_a \\
w_m \\
\theta_m \\
\end{bmatrix}
= 
\begin{bmatrix}
-K_v & -K_i & 0 \\
K_v & 0 & 0 \\
0 & 1 & 0 \\
\end{bmatrix}
\begin{bmatrix}
i_a \\
w_m \\
\theta_m \\
\end{bmatrix}
+ 
\begin{bmatrix}
1/ L_a \\
0 \\
0 \\
\end{bmatrix}
V_c
\]
where all the variables are well known. The damping ratio $\delta$ of a second order system is expressed in terms of the maximum overshoot $M$, as

$$\delta = \sqrt{\frac{(\ln M_p)^2}{\pi^2 + (\ln M_p)^2}}.$$ 

IV. SIMULATION AND RESULTS

A. P-I Controller
The speed and torque of an induction motor is control by P-I controller. PI controller gets one input. The actual speed and reference speed are compared and the error of the speed is given as input to PI controller. Based on the proportional gain value and the integral gain value, the PI controller regulates an output which is given to the inverter triggering switch depending on the load variation.
C. Fuzzy Logic Controller
Fuzzy logic control (FLC) is a control algorithm based on a linguistic control strategy which tries to account the human’s knowledge about how to control a system without requiring a mathematical model [6,7]. The approach of the basic structure of the fuzzy logic controller system is illustrated in FIG. 9

Input and output are non-fuzzy values and the basic configuration of FLC is featured in Fig10. In the system presented in this study, Mamdani type of fuzzy logic is used for speed controller. Inputs for Fuzzy Logic controller are the speed error (e) and change of speed error. Speed error is calculated with comparison between reference speed, \( \omega_{\text{ref}} \) and the actual speed, \( \omega_{\text{act}} \).

V. CONCLUSION
In simulation results, it was shown that PI controller maintained the steady state accuracy while the fuzzy controller performed well in the case of sufficiently large reference input changes with shorter settling time. The IP controller has integrated both fuzzy controller and PI controller. During the large speed error, the fuzzy controller will be selected by switch. The PI controller will be selected to maintain the high steady-state accuracy. The project is intended to demonstrate, the successful application of I-P controller to a phase-controlled converter dc separately excited motor-generator system. I-P controller's performance was compared with that of conventional P-I system. I-P controllers show some important advantages: the overshoot in speed is limited, thus the starting current overshoot is reduced. Also, using the suitable coefficient gains, I-P controllers offer good load recovery characteristics. Moreover, the simulation and experimental studies clearly indicate the superior performance of I-P controller, because it is inherently adaptive in nature. From the above derivation I-P controllers
can replace P-I for the speed control of dc motor drives. The simulation results obtained on a dc motor speed control system using a fuzzy logic controller are presented in the paper. The system uses a basic FLC as well as an improved FLC in which an error interpreter is included. It is seen that the step response with error interpreter has a smaller rise time and a reduced overshoot.
