Abstract

In this paper, a weighted guided image filter (WGIF) is proposed to address the problems faced by the existing methods such as global and local filtering techniques. Local filtering-based edge preserving smoothing techniques suffer from halo artifacts. The global optimization based filters often yield excellent quality, they have high computational cost. The WGIF receives advantages of both global and local smoothing filters in the sense that: 1) the complexity of the WGIF is \( O(N) \) for an image with \( N \) pixels, which is same as the GIF and 2) the WGIF can avoid halo artifacts like the existing global smoothing filters. The WGIF is applied for single image detail enhancement, single image haze removal, and fusion of differently exposed images. Experimental results shows that the resultant image produces better visual quality by reducing/avoiding the halo artifacts to zero.

KEYWORDS: Edge-preserving smoothing, weighted guided image filter, edge aware weighting, detail enhancement, haze removal, exposure fusion

1. INTRODUCTION

In human visual perception, edges provide an effective and expressive stimulation which is important for neural interpretation of a scene. In the fields of image processing and in many computational photography employ smoothing techniques which could preserve edges better. In smoothing process an image to be filtered is typically decomposed into two layers: a base layer composed by homogeneous regions with sharp edges and a detail layer formed by either noise, e.g., a random pattern with zero mean, or texture, e.g, a repeated pattern with usual arrangement. There are two types of edge-preserving image smoothing techniques: global filters such as the weighted least squares (WLS) filter and local filters such as bilateral filter (BF), trilateral filter, and their accelerated versions, as well as guided image filter (GIF). Though the global optimization based filters frequently yield excellent quality, they have high computational cost. Comparing with the global optimization based filters, the local filters are generally simpler. However, the local filters cannot conserve sharp edges like the global optimization based filters.
Halo artifacts were usually produced by the local filters when they were adopted to smooth edges. Major reason that the BF/GIF produces halo artifacts was both spatial similarity parameter and range similarity parameter in the BF were fixed. But both the spatial similarity and the range similarity parameters of the BF could be adaptive to the content of the image to be filtered. Unfortunately as pointed out, problem with adaptation of the parameters will destroy the 3D convolution form. We introduce in present paper, an edge-aware weighting technique and incorporated into the GIF to form a weighted GIF (WGIF). Local variance in 3×3 window of pixel in a guidance image is applied to calculate the edge-aware weighting. The local variance of a pixel is normalized by the local variance of all pixels in guidance image. The normalized weighting is then adopted to design the WGIF. As a result, halo artifacts can be avoided by using the WGIF. Similar to the GIF, the WGIF also avoids gradient reversal. In addition, the intricacy of the WGIF is O(N) for an image with N pixels which is the same as that of the GIF. These features allow many applications of the WGIF for single image detail enhancement, single image mist removal, and fusion of differently exposed images.

2. EDGE PRESERVING SMOOTHING TECHNIQUES

The task of edge-preserving smoothing is to crumble an image X into two parts as follows:

\[ X(p) = \hat{J}(p) + e(p) \]

where \( \hat{J} \) is a reconstructed image formed by uniform regions with sharp edges, \( e \) is noise or texture, and \( p=(x,y) \) is a position. \( \hat{J} \) and \( e \) are called base layer and detail layer, respectively. One of edge-preserving smoothing techniques is based on local filtering. Bilateral filter (BF) is widely used due to its simplicity but suffer from “gradient reversal” artifacts usually observed in detail enhancement of conventional LDR images. Then GIF was introduced to overcome this problem. In this GIF, a guidance image G was used which could be similar to the image X which is to be filtered. \( \hat{J} \) is a linear transform of G in the window \( \Omega \). To determine the linear coefficients \( (a'_p , b'_p) \), a constraint is added to X and \( \hat{J} \) as in Equation (1). The values of \( a'_p \) and \( b'_p \) are then obtained by minimizing a cost function \( E(a'_p , b'_p) \) which is defined as

\[
E = \sum_{p \in \Omega} \left[ (a'_p G(p) + b'_p - X(p))^2 + \lambda \|a'_p\|^2 \right]
\]  

where \( \lambda \) is a regularization parameter.

Another type of edge-preserving smoothing techniques was based on global optimization. The Weighted Least Square filter was a typical example and it was derived by minimizing the following quadratic cost function:

\[
E = \sum_{p=1}^{N} [(f(p) - X(p))^2 + \lambda(p)\|\nabla f(p)\|^2]
\]  

where \( N \) is the total number of pixels in an image. The two major differences between the WLS filter and the GIF

1) The GIF is based on local optimization while the WLS filter in based on global optimization. As such, the difficulty of the GIF is O(N) for an image with N number of pixels and the Weighted Least Square filter is more complicated than the GIF.
2) The value of \( \lambda \) is fixed in the GIF while it is adaptive to local gradients in the WLS filter. One possible problem for the GIF is halos which could be reduced by the WLS filter. The spatial varying image gradients aware weighting \( \lambda_x(p) \) and \( \lambda_y(p) \) are very important for the WLS filter to avoid halo artifacts.

Figure 1(b): Edge of input image

3. EXISTING METHODS

a) Bilateral Filter

The bilateral filter was perhaps the simplest which computed the filtering output at each pixel as the average of near-by pixels, weighted by the Gaussian of both range and spatial distance. The bilateral filter smooth’s the image while preserving edges. Constraint of the bilateral filter was it endure from “gradient reversal” artifacts. The reason was that when a pixel (often on an edge) has few similar pixels around it, the Gaussian weighted average is unstable. Efficiency was another problem regarding the bilateral filter.

b) Non-average Filter

Edge-preserving filtering could also be achieved by non average filters. The median filter was a familiar edge-aware operator, and was a special case of local histogram filters. Histogram filters had \( O(N) \) time implementations in a way as the bilateral grid. The non-average filters were often computationally expensive.

c) Guided Image Filter

A general linear translation-variant filtering process, which involved a guidance image \( I \), an filtering input image \( p \), and an output image \( q \). The filtering output at a pixel \( I \) was expressed as a weighted average:

\[
q_i = \sum_j W_{ij}(I)p_j \quad (4)
\]

where \( i \) and \( j \) were pixel indexes. The filter kernel \( W_{ij} \) was a function of the guidance image \( I \) and independent of \( p \). This filter was linear with respect to \( p \).
d) Adaptive Bilateral Filter

Both range similarity parameter and spatial similarity parameter were adaptive to the content of filtered image. However, adaptation of the parameters destroyed the 3-D convolution form. It was time consuming to extract fine details from a set of differently exposed images by the content adaptive bilateral filters because each input image needed to be decomposed individually. A content adaptive bilateral filter was proposed in gradient domain by taking the characteristics of the human visual system into consideration.

e) Adaptive Guided Image Filter

An adaptive guided image filtering (AGF) able to perform halo-free edge slope enhancement and noise reduction simultaneously. The intensity range domain of BLF and kernel function of GIF were similar in principle, because each of them takes the intensity value of center pixel p, local neighbors q and a smoothing parameter (σr in BLF, ε in GIF) in the computation process. This was based on the shifting technique of ABF, in which the offset ξp was added to the intensity value of center pixel pin the intensity range domain of BLF. The same strategy was applied to AGF - the offset is added to the intensity value of center pixel pin the kernel weights function of GIF.

4. PROPOSED METHOD

In this, an edge-aware weighting is first proposed and it is incorporated into the GIF to form the WGIF.

A) An Edge-Aware Weighting

Let G be a guidance image and be the variance of G in the 3 × 3 window,. An edge-aware weighting is defined by using local variances of 3 × 3 windows of all pixels as follows

$$\Gamma_G(p)=\frac{1}{N}\sum_{p=1}^{N}\sigma^2_{G_1}(p)+\xi$$

(5)

Where ε is a small constant and its value is selected while L is the dynamic range of the input image.

In addition, the weighting $$\Gamma_G(p)$$ measures the importance of pixel p with respect to the whole guidance image. Due to the box filter, the complexity of $$\Gamma_G(p)$$ is O(N) for an image with N pixels. The value of $$\Gamma_G(p)$$ is usually larger than 1 if p is at an edge and smaller than 1 if p is in a smooth area. Clearly, larger weights are assigned to pixels at edges than those pixels in flat areas by using the weight $$\Gamma_G(p)$$ in Equation (5).

B) The Proposed Filter

Same as the GIF, the key assumption of the WGIF is a local linear model between the guidance image G and the filtering output ̂Z as in Equation (2). The model ensures that the output ̂Z has an edge only if the guidance image G has an edge. The proposed weighting G(p) in Equation (5) is incorporated into the cost function E(a p, b p) in Equation (3). As such, the solution is obtained by minimizing the difference between the image to be filtered X and the filtering output ̂Z while maintaining the linear model (2), i.e., by minimizing a cost function E(a p, b p) which is defined as

$$E = \sum_{p=-\Omega}^{\Omega} \left[ (a_p \cdot G(p) + b_p \cdot \frac{X(p) - X(p)}{\mu(p)})^2 + \frac{1}{\lambda} \right]$$

(6)

The optimal values of a p and b p are computed as

$$a_p = \frac{\mu_{G \odot X, \xi_1}(p) - \mu_{G, \xi_1}(p)}{\sigma^2_{G, \xi_1}(p) + \lambda \cdot \Gamma_G(p)}$$

(7)

$$b_p = \mu_{X, \xi_1}(p) - a_p \cdot \mu_{G, \xi_1}(p)$$

(8)
where $\odot$ is the element-by-element product of two matrices. $\mu_{G \odot X, \xi}(p)$, $\mu_{G, \xi}(p)$, and $\mu_{X, \xi}(p)$ are the mean values of $G \odot X$, $G$, and $X$, respectively.

The final value of $Z^*(p)$ is given as follows:

$$Z(p) = \hat{a}_p G(p) + \hat{b}_p \quad (9)$$

Where $\hat{a}_p$ and $\hat{b}_p$ are the mean values of and in the window computed as

$$\hat{a}_p = \frac{1}{|\Omega_p|} \sum_{\xi \in \Omega_p} a_p ; \quad \hat{b}_p = \frac{1}{|\Omega_p|} \sum_{\xi \in \Omega_p} b_p \quad (10)$$

And $|\Omega_p|$ is the cardinality of $\Omega_p$.

C. Single Image Haze Removal

Images of outdoor scenes could be degraded by haze, fog, and smoke in the atmosphere. The degraded images lose the contrast and color fidelity. Haze removal is thus highly desired in both computational photography and computer vision applications. The model adopted to describe the formulation of a haze image is given as

$$X_c(p) = Z_c(p) t(p) + A_c (1 - t(p)) \quad (10)$$

When the atmosphere is homogenous, the transmission $t(p)$ can be expressed as:

$$t(p) = e^{-a_d(p)} \quad (11)$$

Let $\phi_c(.)$ be a minimal operation along the color channel $\{r, g, b\}$ and it is defined as

$$A_{\min} = \phi_c (A_c) = \min\{A_r, A_g, A_b\} \quad (12)$$

$$X_{\min}(p) = \phi_c (X_c(p)) \quad (13)$$

$$Z_{\min}(p) = \phi_c (Z_c(p)) \quad (14)$$

It can be derived from the haze image model in Equation (15) that

$$X_{\min}(p) = Z_{\min}(p) t(p) + A_{\min} (1 - t(p)) \quad (15)$$

Let $\psi_{\zeta_2}(.)$ be a minimal operation in the neighborhood $\psi_{\zeta_2}(p)$ and it is defined as

$$\psi_{\zeta_2}(x(p)) = \min_{p \in \Omega_{\zeta_2}(p)} \{x(p)\} \quad (16)$$

It is shown that the complexity of $\psi_{\zeta_2}(.)$ is $O(N)$ for an image with $N$ pixels. The dark channel is defined as

$$J^2_{\text{dark}}(p) = \phi_c (\psi_{\zeta_2}(Z_c(p))) \quad (17)$$

where the value of $\zeta_2$ is 7. Even though the complexity of $\psi_{\zeta_2}(.)$ is $O(N)$ for an image with $N$ pixels, three minimal operations $\psi_{\zeta_2}(.)$ and one minimal operation $\phi_c(.)$ are required to compute $J^2_{\text{dark}}(p)$ for the pixel $p$. Simplified dark channel is defined as

$$J^2_{\text{dark}}(p) = \psi_{\zeta_2}(\phi_c (Z_c(p))) \quad (18)$$

The value of $t(p)$ is assumed to be constant in the neighborhood $\Omega_{\zeta_2}(p)$. It can be derived from Equation (20) that

$$J_{\text{dark}}(p) = J^2_{\text{dark}}(p) t(p) + A_{\min} (1 - t(p)) \quad (19)$$

Since $J^2_{\text{dark}}(p) \approx 0$, the value of $t(p)$ can be initially estimated as

$$t(p) = \frac{1 - J^2_{\text{dark}}(p)}{A_{\min}} \quad (20)$$

It is worth noting that the initial value of $t(\ p)$ is given as

$$t(p) = 1 - \phi_c (\psi_{\zeta_2}(\frac{Z_c(p)}{A_c})) \quad (21)$$

The initial value of $t(p)$ is then computed as

$$t(p) = 1 - \frac{31}{32} \frac{J^2_{\text{dark}}(p)}{A_{\min}} \quad (22)$$
The value of $\lambda$ is set to $1/1000$ and the value of $\zeta_1$ to 60. The value of the transmission map $t(p)$ is further adjusted as

$$t(p) = t^{1+\zeta}(p)$$ (23)

where the value of $\zeta$ is adaptive to the haze level of the input image. Its value is $0/0.03125/0.0625$ if the input image is with light/normal/heavy haze.

Finally, the scene radiance $Z(p)$ is recovered by

$$\hat{Z}_c(p) = \frac{X_c(p) - A_c}{t(p)} + A_c; c \epsilon \{r, g, b\}$$ (24)

Equation (29) is equivalent to

$$\hat{Z}_c(p) = X_c(p)$$

$$+ \left( \frac{1}{t(p)} - 1 \right) (X_c(p) - A_c)$$ (25)

Since the color of the sky is usually very similar to the atmospheric light $A_c$ in a haze image, it can be shown that

$$\frac{f_{\text{dark}}(p)}{A_{\text{min}}} \rightarrow 1, \text{ and } \frac{1}{t(p)} - 1 \rightarrow 31$$ (26)

### D. Fusion of Differently Exposed Images

One of the challenges in digital image processing research is the rendering of a HDR natural scene on a conventional LDR display. This challenge can be addressed by capturing multiple LDR images at different exposure levels. Each LDR image only records a small portion of the dynamic range and partial scene details but the whole set of LDR images collectively contain all scene details. All the differently exposed images can be fused together to produce a LDR image by an exposure fusion algorithm. Similar to the detail enhancement of a LDR image, halo artifacts, gradient reversal artifacts and amplification of noise in smooth regions are three major problems to be addressed for the fusion of differently exposed images.

### 5. SIMULATION RESULTS

**Figure 2:** (a) Input image (b) Guided image (c) Enhanced image by GIF (d) Enhanced image by WGIF

**Analysis 2:** In the above figure first is the input image which is to be analyzed and the second is guided image which is not but a filtering technique which preserves the edges of an image, the third one is GIF image with less preserving edges. The last one is proposed method which shows image with zero artifacts.

**Figure 3:** Weighted image

**Analysis 3:** The above applies weights on the edges of an image to preserve edges of an image occurred by the filtering technique.
Figure 4: (a) Input image (b) Guided image (c) Dehazed image by GIF (d) Dehazed image by WGIF
Analysis 4: The above figure is used to dehaze the image from smoke etc as shown by applying different techniques.

Figure 5: (a) Input HDR (b) Enhanced with WGIS (c) Enhanced with GIS
Analysis 5: This figure is used to show the enhancement of an image with improved picture quality by different edge preserving techniques.

6. EXTENSION

Proposed method has been performed improved image quality on images. For extension, we are performing on videos. Compare to images the complexity for videos is more because a video consist of no. of frames. As the no. of frames increases the reduction of complexity is also gets increased. But, avoiding all these complexities every frame is avoiding halo artifacts and preserves edges. At last all these frames converted into video.

Figure 6: Input video
Analysis 6: The above figure shows the input video which consist of some set of frames.

Figure 7: GI Video
Analysis 7: The above figure shows GI video which has better results than the input video.
7. CONCLUSION

This method is introduced by incorporating an edge-aware weighted into an existing guided image filter (GIF). It has two advantages of both global and local smoothening filter in the sense-(1) Its complexity is 0,(2)Avoid halo artifacts The output of WGIF results in better visual quality and avoid halo artifacts. , it has many applications in the fields of computational photography and image processing. Particularly, it is applied to study single image detail enhancement, single image haze removal, and fusion of differently exposed images. Experimental results show that the resultant algorithms can produce images with excellent visual quality as those of global filters, and at the same time the running times of the proposed algorithms are comparable to the GIF based algorithms. It is noting that the WGIF can also be adopted to design a fast local tone mapping algorithm for high dynamic range images, joint up sampling, flash/no-flash de-noising, and etc. In addition, similar idea can be used to improve the anisotropic diffusion, Poisson image editing, etc. All these research problems will be studied in our future research.
