Abstract—this paper focused on modeling and simulation of grid connected photovoltaic system. This work presents a fuzzy logic control based maximum power point tracking approach to enhance the efficiency and robustness of the solar photovoltaic (PV) power generation and establishes a dynamic model of grid-connected PV system by Matlab/Simulink environment which reflect the characteristics of the system accurately. Grid-connected PV system includes a PV array, dc-dc converter, fuzzy logic control based MPPT, inverter, LC filter, P-Q based inverter control, a distribution network. Improved fuzzy logic control based MPPT and P and Q based inverter control scheme provides a closed loop active and reactive power control and accurate synchronization to grid. In this paper, a micro inverter with PI and fuzzy based boost converter approach is presented which enables the designer to make use of the boost converters advantages, while improving the control difficulties. This control method allows the selection of passive components predominantly based on ripple and reliability specifications while requiring only one state reference signal. This method becomes smaller and more reliable.

Keywords: Photovoltaic array, Modeling, Grid-connected photovoltaic system, MPPT control, Power inverter.

I. INTRODUCTION

The much concerned with the fossil fuel exhaustion and the environmental problems are caused by the conventional power generation. Nowadays, renewable energy sources, such as photovoltaic (PV) panels and wind-generators, are now widely used. PV systems are the most direct way to convert solar radiation into electricity and are based on the PV effect, which was first observed by Henri Becquerel in 1839. It is quite generally defined as the emergence of an electric voltage between two electrodes attached to a solid or liquid system upon shining light onto this system. Practically, all PV devices incorporate a PN junction in a semiconductor across which the photo voltage is developed [1-2]. These devices are also known as solar cells. Light absorption occurs in a semiconductor material. The semiconductor material has to be able to absorb a large part of the solar spectrum [3].

The increasing of the world energy demand, due to the modern industrial society and population growth, is motivating a lot of investments in alternative energy solutions, in order to improve energy efficiency and power quality issues. The use of photovoltaic energy is considered to be a primary resource, because there are several countries located in tropical and temperate regions, where the direct solar density may reach up to 1000 W/m2. At present, photovoltaic (PV) generation is assuming increased importance as a renewable energy sources application because of distinctive advantages such as simplicity of allocation, high dependable, absence of fuel cost, low maintenance and lack of noise and wear due to the absence of moving parts [10]. The cell conversion ranges vary from 12 percentage of efficiency up to a maximum of 29 percentages for very expensive units [11]. In spite of those facts, there has been a trend in price decreasing for modern power electronics systems and photovoltaic cells, indicating good promises.
for new installations. However, the disadvantage is that photovoltaic generation is intermittent, depending upon weather conditions. Thus, the MPPT makes the PV system providing its maximum power and to help get stable and reliable power from PV system for both loads and utility grid, and thus improve both steady and dynamic behaviors of the whole generation system [12]. In this paper I have studied a grid-connected photovoltaic generation system which is composed of PV array, power electronic converters, filter, controllers, local loads and utility grid as shown in figure.

![Fig 1: Block diagram of grid connected PV system.](image1)

The block diagram representation of grid connected PV system is given in figure.1. In this PV array is connected to dc-dc converter. The switching pulses for dc-dc converter is generated by fuzzy logic control based MPPT and gate generator arrangement. By using feedback voltage and power taken from the PV array, fuzzy logic control based MPPT produces a reference for the converter and using this reference, PWM generator produces switching signal for the dc-dc converter. These reference signals are given to sinusoidal PWM generator which produces six switching pulses for the inverter. The overall system uses a high efficiency fuzzy logic control based MPPT and buck converter, produces PV array voltage corresponding to the maximum power. The three phase inverter with P-Q control and LC filter produces sinusoidal ac voltage and current having less THD.

II. SIMULATION MODELS

Modeling and simulating PV power systems are investigated in this section. By default, all symbols that are used in equations refer to the definition table shown in the Nomenclature.

A. Modeling Photovoltaic Cells

The ideal single-diode model (ISDM) which is shown in Fig.2 was proposed to represent PV outputs for crystalline-based solar cells. The simplified model shows computational efficiency but provides fewer tuning parameters in comparison with the standard single-diode model that was presented in [11]–[13]. The model parameters should be properly identified, and the modeling accuracy should be evaluated carefully before it is integrated into system simulation. The I–V characteristic for an ISDM is expressed as

\[ i_{PV} = i_{ph} - i_s \left( e^{\left( \frac{qV_{PV}}{kAT_{CS}} \right)} - 1 \right) \]  

(1)

The definition of variables and constants in (1) refers to the nomenclature table. A is an unknown parameter that needs to be identified. Since the prior work in did not give a clear illustration for parameter extraction and simulation construction, the parameterization and model implementation are shown in the following sections.

![Fig. 2. Equivalent circuit for the ideal single-diode PV-cell model.](image2)

B. Photovoltaic Model Parameterization

PV manufacturers provide the values of open-circuit voltage (VOCS), short-circuit current (ISCS), and the maximum power point (VMPP, IMPP) at STC. According to the equivalent circuit of ISDM, the value of the photon current \( i_{ph} \) is equal to that of the short-circuit current ISCS at STC. When the solar cell is open-circuited, the output current of a PV cell is zero. Therefore, the I–V characteristics at STC can be expressed as

\[ I_{SS} = \frac{I_{SCS}}{e^{\left( \frac{qV_{OCS}}{kAT_{CS}} \right)} - 1} \]  

(2)

At the MPP of STC, the I–V characteristic equation can be expressed as

\[ I_{MPP} = I_{SCS} - I_{SS} \left[ e^{\left( \frac{qV_{MPP}}{kAT_{CS}} \right)} - 1 \right] \]  

(3)

Therefore, the ideality factor A can be derived from (4), shown below, by the substitution of (2) into (3):

\[ \frac{qV_{MPP}}{e^{\left( \frac{qV_{OCS}}{kAT_{CS}} \right)} - 1} = 1 - \frac{I_{MPP}}{I_{SCS}} \]  

(4)

The diode saturation current \( I_{SS} \) can be found by applying Aback to (2). Thus, the I–V characteristics at STC can be expressed as (5), shown below, where the photon current and saturation current are constant:
\[ i_{PV} = I_{SCS} - I_{SS} \left[ e^{\left(\frac{q_{PV} E_e}{k T_{CS}}\right)} - 1 \right] \]  
\h{5}

C. Photovoltaic Model Construction for Simulation

Both the photon current and saturation current change with the solar radiation and cell temperature. For the irradiance deviated from STC, the expression of \( i_{ph} \) can be written as

\[ i_{ph}(E_e, \Delta T) = \frac{E_e}{E_{STC}} I_{SCS} (1 + \alpha T \Delta T) \]  
\h{6}

Where the definitions of \( E_e \) and \( E_{STC} \) refer to the nomenclature table. \( \Delta T \) is the temperature difference between the cell temperature \( T_C \) and the STC temperature \( T_{CS} \), and \( \alpha T \) is the current temperature coefficient that is given by the product datasheet. The expression in (6) shows that the photon current varies with both solar irradiance and cell temperature. The open-circuit voltage can be derived as

\[ V_{OC}(\Delta E_e, \Delta T) = V_{OCS} (1 + \beta T \Delta T)(1 + \gamma E \Delta E_e) \]  
\h{7}

Where the definitions of \( \beta T \) and \( \gamma E \) and \( E_e \) and \( E_{STC} \) refer to the nomenclature. \( \Delta E_e \) is the irradiance difference from the STC, and \( \beta T \) is given by the product datasheet. The irradiance coefficient on voltage \( \gamma E \) can be determined from the evaluation of the I–V curves for various insulation levels. For example, the open-circuit voltage is given as \( V_{OC} \), when the irradiance is \( 0.8 \) kW/m\(^2\), and the cell temperature is \( 25^\circ \text{C} \). The value of \( \gamma E \) can be estimated as

\[ \gamma E = \left(\frac{V_{OC, 0.8}}{V_{OCS}} - 1\right) / (1 - 0.8) \]  
\h{8}

Therefore, the diode saturation current can be updated by following the environmental variation, which is shown as

\[ i_S(\Delta E_e, \Delta T) = \frac{i_{ph}(E_e, \Delta T)}{e^{\left(\frac{q V_{OC}(\Delta E_e, \Delta T)}{k T_{CS} + \Delta T}\right)} - 1} \]  
\h{9}

The I–V characteristic equation can be written as (10), shown below, corresponding to the variation of the solar irradiance and cell temperature

\[ i_{PV} = i_{ph}(E_e, \Delta T) - i_s(\Delta E_e, \Delta T) e^{\left(\frac{q V_{PV}(\Delta E_e, \Delta T)}{k T_{CS} + \Delta T}\right)} - 1 \]  
\h{10}

D. Terminal Output Implementation

The single-cell model can be aggregated to any size of a PV array, as shown in Fig. 3. \( N_s \) and \( N_p \) are the numbers of cells that are connected in series and parallel, respectively. When the mathematical representation is combined with a controllable current resource, the model gives terminal outputs regarding to voltage and current \( V_{pv} \) and \( I_{pv} \) which are compatible with the majority of off-the-shelf circuit-based simulation tools, such as the SimPowerSystems for Simulink, PSIM, PSPICE, PSCAD, etc. The equation, i.e., \( i_{pv} = f(\nu_{pv}, E_e, \Delta T) \), is updated every simulation step following (10) and operating variation. A generalized simulation flowchart is illustrated in Fig.4.

![Flowchart of the PV model simulation.](image)

Unlike the proposed PV model in [1]–[3], the simplified model ignores the coupled terms between \( i_{pv} \) and \( \nu_{pv} \). \( E_e \) and \( \Delta T \) are the environmental variables. The value of \( \nu_{pv} \) is determined by the power equilibrium between the PV generation and load, which is regulated by the interconnected power interface. Therefore, a more efficient simulation can be expected since no iterative solver is needed.

E. Interfacing with Intermediate DC Link

For two-stage conversion topologies, as shown in Fig. 1 (a), the non-isolated dc/dc boost topology is commonly used as the PV front-end power converter (PVFEC) because of the voltage step-up requirement and its simplicity. The control of the PVFEC is the MPPT. One study indicates that the boost topology is superior over the buck in terms of cheaper implementation and better dynamics. The circuit diagram can be depicted as Fig.5,
where the PV-array model refers to the diagram in Fig. 2, and the IDCL capacitor $C_{dc}$ is the joint connection to dc/ac inverter.

![Diagram of PV array model, MPPT power interface, and DC link](image)

Fig. 5. Circuit schematics showing the combination of the PV array and the DC link.

Averaged models show advantages of fast simulation if the system switching harmonics are not concerned. This feature is important to simulate a large power system with multiple inverter-based generators. Assuming that the dc/dc converter works in continuous conduction mode (CCM), the averaged model can be derived as

\[
\begin{align*}
C_{PV} \frac{dV_{PV}}{dt} &= I_{PV} - i_L \\
L \frac{di_L}{dt} &= V_{PV} - (1 - d)V_{dc} \\
C_{dc} \frac{dV_{dc}}{dt} &= i_{dc} - i_{INV}
\end{align*}
\]

Following the expression in (11), the averaged model can be constructed as shown in Fig. 6, where the input variable is the injection current to the grid inverter $i_{INV}$, the control variable is the duty cycle $d$, and the state variables include $V_{dc}$, $V_{PV}$, and $i_L$. The environmental inputs that comprise $E_n$ and $\Delta T$ affect the PV-array model output. For the presented two-stage power conversion with IDCL, the values of $d$ and $i_{INV}$ are determined by the MPPT function and $V_{dc}$ regulation, respectively.

![Diagram of implementation of the averaged model in CCM combining the PV array and the boost converter power interface](image)

Fig. 6. Implementation of the averaged model in CCM combining the PV array and the boost converter power interface.

The output power of dc/ac grid inverters $P_{ac}$ can be estimated as (12), shown below, where the conversion efficiency $\eta$ can be determined by (13), shown below, applying the peak conversion Efficiency $\eta_{max}$ and the self-power consumption $P_{self}$.

\[
P_{ac} = \eta P_{pv} \text{ or } P_{ac} = \eta V_{pv} I_{pv}
\]

\[
\eta = \frac{(P_{pv} - P_{self}) \times \eta_{max}}{P_{pv}}
\]

$P_{self}$ is accumulated power loss that results from microcontrollers, drive circuits, human machine interfaces, other accessories, etc. Since the grid-side voltage is known and steady, the RMS value of the ac injection current can be calculated.

**F. Interfacing with Grid without IDCL**

String inverters show significant generation degradation that results from PV module mismatch and partial shading. The emerging solution is the MIC, which is also called the micro inverter, to eliminate the power loss that results from inconsistent impacts. A specific MIC, which is shown in Fig. 7 and adopting the interleaved fly back topology, is considered in this study. The topology offers the advantages of high efficiency, reliability, power sharing, galvanic isolation, and reduced PV voltage ripple. Therein, all the details about the converter operation can be found.

![Diagram of topology of the interleaved fly back MIC for solar grid-tied systems](image)

Fig. 7. Topology of the interleaved fly back MIC for solar grid-tied systems.

The simulation model of the MIC is developed by the averaging technique. The model diagram is shown in Fig. 8, where $D$ represents the duty cycle, and $D1$ is defined as $1 - D$. The fourth-order dynamic system includes four state variables, $V_{pv}$, $V_{Cf}$, $I_f$, and $I_{inv}$, which result from the input and output storage units and illustrated in the shadowed boxes. In Fig. 3.8, the boxes with broken lines represent the system inputs, and the duty cycle $D$ is the control variable. The variables $V_{pv}$ and $I_{pv}$ are associated
with the PV-panel model, which is presented in Section II.

**G. Dynamic Model of Maximum Power Point Tracking**

The voltage of the optimal operating point (VOOP) is the index that represents the MPP. In this study, it is estimated as

$$V_{OOP}(\Delta E_e, \Delta T) = V_{MPP}(1 + \beta_T \Delta T)(1 + \gamma_E \Delta E_e)$$

(14)

Where the definitions of $\beta_T$ and $\gamma_E$ refer to the nomenclature table. $\Delta E_e$ is the irradiance difference from the STC. The temperature coefficient can be directly obtained from the product datasheet. The irradiance coefficient on voltage can be determined the evaluation of $I-V$ curves that are based on various insolation levels.

One of the commonly used MPPT algorithms is the perturbation and observation (P&O) method, which applies two parameters, the perturbation time interval $\Delta T$ MPPT and perturbation amplitude $\Delta T$. Thus, the MPP tracking dynamics are implemented by a slew-rate limiter, as expressed in (15), shown below, which defines the maximum rate of the set point change.

$$SR = \frac{\Delta V}{\Delta T_{MPPT}}$$

(15)

As a result, the MPPT operation can be simplified as the diagram shown in Fig.9, where the optimal operating point is calculated by (14), and the slew-rate limiter mimics the MPP tracking dynamics.

**III. FUZZY LOGIC CONTROL**

L. A. Zadeh presented the first paper on fuzzy set theory in 1965. Since then, a new language was developed to describe the fuzzy properties of reality, which are very difficult and sometime even impossible to be described using conventional methods. Fuzzy set theory has been widely used in the control area with some application to power system [5]. A simple fuzzy logic control is built up by a group of rules based on the human knowledge of system behavior. Matlab/Simulink simulation model is built to study the dynamic behavior of converter. Furthermore, design of fuzzy logic controller can provide desirable both small signal and large signal dynamic performance at same time, which is not possible with linear control technique. Thus, fuzzy logic controller has been potential ability to improve the robustness of compensator.

The basic scheme of a fuzzy logic controller is shown in Fig.10 and consists of four principal components such as: a fuzzy fication interface, which converts input data into suitable linguistic values; a knowledge base, which consists of a data base with the necessary linguistic definitions and the control rule set; a decision-making logic which, simulating a human decision process, infer the fuzzy control action from the knowledge of the control rules and linguistic variable definitions; a defuzzification interface which yields non fuzzy control action from an inferred fuzzy control action [10].

**Rule Base:** the elements of this rule base table are determined based on the theory that in the transient state, large errors need coarse control, which requires coarse input/output variables; in the steady state, small errors need fine control, which requires fine input/output variables.
Based on this, the elements of the rule table are obtained as shown in Table, with ‘Vdc’ and ‘Vdc-ref’ as inputs.

V. CONCLUSION

This paper presents a technique to design and control of grid-connected PV generation system, identify its components, and describe how it works. In order to convert the solar energy efficiently, the MPPT algorithm for photovoltaic systems based on P&O algorithm has been presented. It should be tracked to ensure the PV array to generate most power to utility grid, and describe the following control algorithms used for the inverter DC-AC for regulate active and reactive power at connection bus. This paper has presented a general approach to modeling and simulating PV power systems with regard to electrical engineering perspectives. A simplified PV model is developed showing the detailed parameterization, which is based on the given information of the manufacturer datasheet. Since the majority of PV power system is grid-tied, the modeling process focuses on two common power interfaces that include the two stage power conversion with IDCL and single-stage conversion without IDCL. The MIC that is called “micro inverter” is also included for the simulation study. Detailed model of grid-connected photovoltaic generation system components, in MATLAB/Simulink software was done. Fuzzy controlled MPPT strategy is used for PV output voltage to achieve closed loop control which can smoothly and quickly track the maximum power point of PV array.
